Caches
The Memory Hierarchy

Want large, fast, and cheap memory, but...

Large memories are slow (e.g., Hard Disk)
Fast memories are small and expensive (e.g., SRAM)

Solution: Use a hierarchy of memories with different tradeoffs to fake a large, fast, cheap memory

<table>
<thead>
<tr>
<th>Speed</th>

CPU  ≈  Mem
Memory Hierarchy Interface

- Programming model: Single memory, single address space
Memory Hierarchy Interface

- Programming model: Single memory, single address space
- Machine transparently stores data in fast or slow memory, depending on usage patterns
Caches

- **Cache**: A small, interim storage component that transparently retains (caches) data from recently accessed locations.

- **Processor sends accesses to cache. Two options:**
  - **Cache hit**: Data for this address in cache, returned quickly.
  - **Cache miss**: Data not in cache.
    - Fetch data from memory, send it back to processor.
    - Retain this data in the cache (replacing some other data).
  - Processor must deal with variable memory access time.
Why Caches Work

- Two predictable properties of memory accesses:
  - Temporal locality: If a location has been accessed recently, it is likely to be accessed (reused) soon
  - Spatial locality: If a location has been accessed recently, it is likely that nearby locations will be accessed soon

- Result:
  - High hit rate (low miss ratio)
  - Reduced Average Memory Access Time (AMAT):

\[
AMAT = HitTime + MissRatio \times MissPenalty
\]
Basic Cache Algorithm (Reads)

Q: How do we “search” the cache?

On reference to Mem[X], look for X among cache tags

HIT: X = Tag(i) for some cache line i
Return Data(i)

MISS: X not found in Tag of any cache line
Read Mem[X]
Return Mem[X]
Select a line k to hold Mem[X]
Write Tag(k) = X,
Data(k) = Mem[X]

Direct-Mapped Caches

- Each word in memory maps into a single cache line
- Access (for cache with $2^w$ lines):
  - Index into cache with $W$ address bits (the index bits)
  - Read out valid bit, tag, and data
  - If valid bit $== 1$ and tag matches upper address bits, HIT
- Example 8-line direct-mapped cache:
Example: Direct-Mapped Caches

64-line direct-mapped cache → 64 indices → 6 index bits

Read Mem[0x400C]

0100 0000 0000 1100

TAG: 0x40
INDEX: 0x3
BYTE OFFSET: 0x0

HIT, DATA 0x42424242

Would 0x4008 hit?

INDEX: 0x2 → tag mismatch → MISS

Part of the address (index bits) is encoded in the location Tag + Index bits unambiguously identify the data’s address
Selection of Index Bits

Why do we chose low order bits for index?

- Allows consecutive memory locations to live in the cache simultaneously
- Reduces likelihood of replacing data that may be accessed again in the near future
- Helps take advantage of locality
Take advantage of spatial locality: Store multiple words per data line
- Always fetch entire block (multiple words) from memory
- Another advantage: Reduces size of tag memory!
- Potential disadvantage: Fewer indices in the cache

Example: 4-block, 16-word direct-mapped cache
Block Size Tradeoffs

- Larger block sizes...
  - Take advantage of spatial locality
  - Incur larger miss penalty since it takes longer to transfer the block from memory
  - Can increase the average hit time and miss ratio
- AMAT = HitTime + MissPenalty*MissRatio
**Direct-Mapped Cache Problem: Conflict Misses**

Assume:
- 1024-line DM cache
- Block size = 1 word
- Consider looping code, in steady state
- Assume WORD, not BYTE, addressing

Inflexible mapping (each address can only be in one cache location) → Conflict misses (multiple addresses map to same cache index)!

</table>
Fully-Associative Cache

Opposite extreme: Any address can be in any location
- No cache index!
- \textbf{Flexible} (no conflict misses)
- \textbf{Expensive}: Must compare tags of all entries in parallel to find matching one

32-bit BYTE address

N-way Set-Associative Cache

- Use multiple direct-mapped caches in parallel to reduce conflict misses
- Nomenclature:
  - # Rows = # Sets
  - # Columns = # Ways
  - Set size = #ways = “set associativity” (e.g., 4-way → 4 lines/set)
- Each address maps to only one set, but can be in any way within the set
- Tags from all ways are checked in parallel

- Fully-associative cache: Extreme case with a single set and as many ways as cache lines
Associativity Implies Choices

**Issue: Replacement Policy**

Direct-mapped

- Compare addr with only one tag
- Location A can be stored in exactly one cache line

N-way set-associative

- Compare addr with N tags simultaneously
- Location A can be stored in exactly one set, but in any of the N cache lines belonging to that set

Fully associative

- Compare addr with each tag simultaneously
- Location A can be stored in any cache line
Replacement Policies

- **Optimal policy**: Replace the line that is accessed furthest in the future
  - Requires knowing the future...
- **Idea**: Predict the future from looking at the past
  - If a line has not been used recently, it’s often less likely to be accessed in the near future (a locality argument)
- **Least Recently Used (LRU)**: Replace the line that was accessed furthest in the past
  - Works well in practice
  - Need to keep ordered list of N items $\rightarrow$ N! orderings $\rightarrow$ $O(\log_2 N!) = O(N \log_2 N)$ “LRU bits” + complex logic
  - Caches often implement cheaper approximations of LRU
- **Other policies**:
  - First-In, First-Out (least recently replaced)
  - Random: Choose a candidate at random
    - Not very good, but does not have adversarial access patterns
Write Policy

**Write-through**: CPU writes are cached, but also written to main memory immediately (stalling the CPU until write is completed). Memory always holds current contents

- **Simple, slow, wastes bandwidth**

**Write-back**: CPU writes are cached, but not written to main memory until we replace the line. Memory contents can be “stale”

- **Fast, low bandwidth, more complex**
- Commonly implemented in current systems
Example: Cache Write-Hit

16-line direct-mapped cache → 4 index bits
Block size = 4 → 2 block offset bits
Write Policy = Write Back
Write: 0x09 to 0x4818

0100 1000 0001 1000

Tag: 0x48
Index: 0x1
Block Off: 2
Byte Off: 0x0

D=1: cache contents no longer match main memory so write back line to memory upon replacement
**Example: Cache Write-Miss**

**Write: 0x09 to 0x4818**

1. **Tags don’t match -> Miss**
   - D=1: Write cache line 1 (tag = 0x280: addresses 0x28010-0x2801C) back to memory
   - If D=0: Don’t need to write line back to memory.

2. Load line (tag = 0x48: addresses 0x4810-0x481C) from memory

3. Write 0x09 to 0x4818 (block offset 2), set D=1.
Summary: Cache Tradeoffs

\[ AMAT = \text{HitTime} + \text{MissRatio} \times \text{MissPenalty} \]

- Cache size
- Block size
- Associativity
- Replacement policy
- Write policy
Example: Comparing Hit Rates

3 Caches: DM, 2-Way, FA: each has 8 words, block size=1, LRU
Access following addresses repeatedly: 0x0, 0x10, 0x4, 0x24

DM

M[0x0]

M[0x4] M[0x24]

M[0x10]

2-Way

M[0x0]

M[0x4] M[0x24]

M[0x10]

FA

M[0x0]

M[0x10]

M[0x4]

M[0x24]

DM: 50% hit rate
2-Way: 100% hit rate
FA: 100% hit rate

0x0 = 0b000000
DM index = 000
2-Way index = 00

0x10 = 0b010100
DM index = 001
2-Way index = 01

0x4 = 0b000100
DM index = 001
2-Way index = 01

0x24 = 0b100100
DM index = 001
2-Way index = 01
Example 2: Comparing Hit Rates

Access: 0x0, 0x4, 0x8, 0xC, 0x10, 0x14, 0x18, 0x1C, 0x20 repeatedly

DM

\[
\begin{align*}
&M[0x0] \\
&M[0x20] \\
&M[0x4] \\
&M[0x8] \\
&M[0xC] \\
&M[0x10] \\
&M[0x14] \\
&M[0x18] \\
&M[0x1C] \\
\end{align*}
\]

DM: Hit rate = 7/9

2-Way

\[
\begin{align*}
&M[0x0] \\
&M[0x20] \\
&M[0x10] \\
&M[0x4] \\
&M[0x18] \\
&M[0xC] \\
&M[0x0] \\
&M[0x20] \\
&M[0xC] \\
\end{align*}
\]

2-Way: Hit rate = 6/9

FA

\[
\begin{align*}
&M[0x0] M[0x20] \\
&M[0x4] M[0x0] \\
&M[0x8] M[0x4] \\
&M[0xC] M[0x8] \\
&M[0x10] M[0xC] \\
&M[0x14] M[0x10] \\
&M[0x18] M[0x14] \\
&M[0x1C] M[0x18] \\
\end{align*}
\]

FA: Hit rate = 0%
### Example 3: Comparing Hit Rates

**Access:** 0x0, 0x4, 0x8, 0xC, 0x20, 0x24, 0x28, 0x2C, 0x10 repeatedly

<table>
<thead>
<tr>
<th>DM</th>
<th>2-Way</th>
<th>FA</th>
</tr>
</thead>
<tbody>
<tr>
<td>M[0x0]</td>
<td>M[0x0]</td>
<td>M[0x0]</td>
</tr>
<tr>
<td>M[0x20]</td>
<td>M[0x20]</td>
<td>M[0x10]</td>
</tr>
<tr>
<td>M[0x4]</td>
<td>M[0x4]</td>
<td>M[0x4]</td>
</tr>
<tr>
<td>M[0x8]</td>
<td>M[0x8]</td>
<td>M[0x8]</td>
</tr>
<tr>
