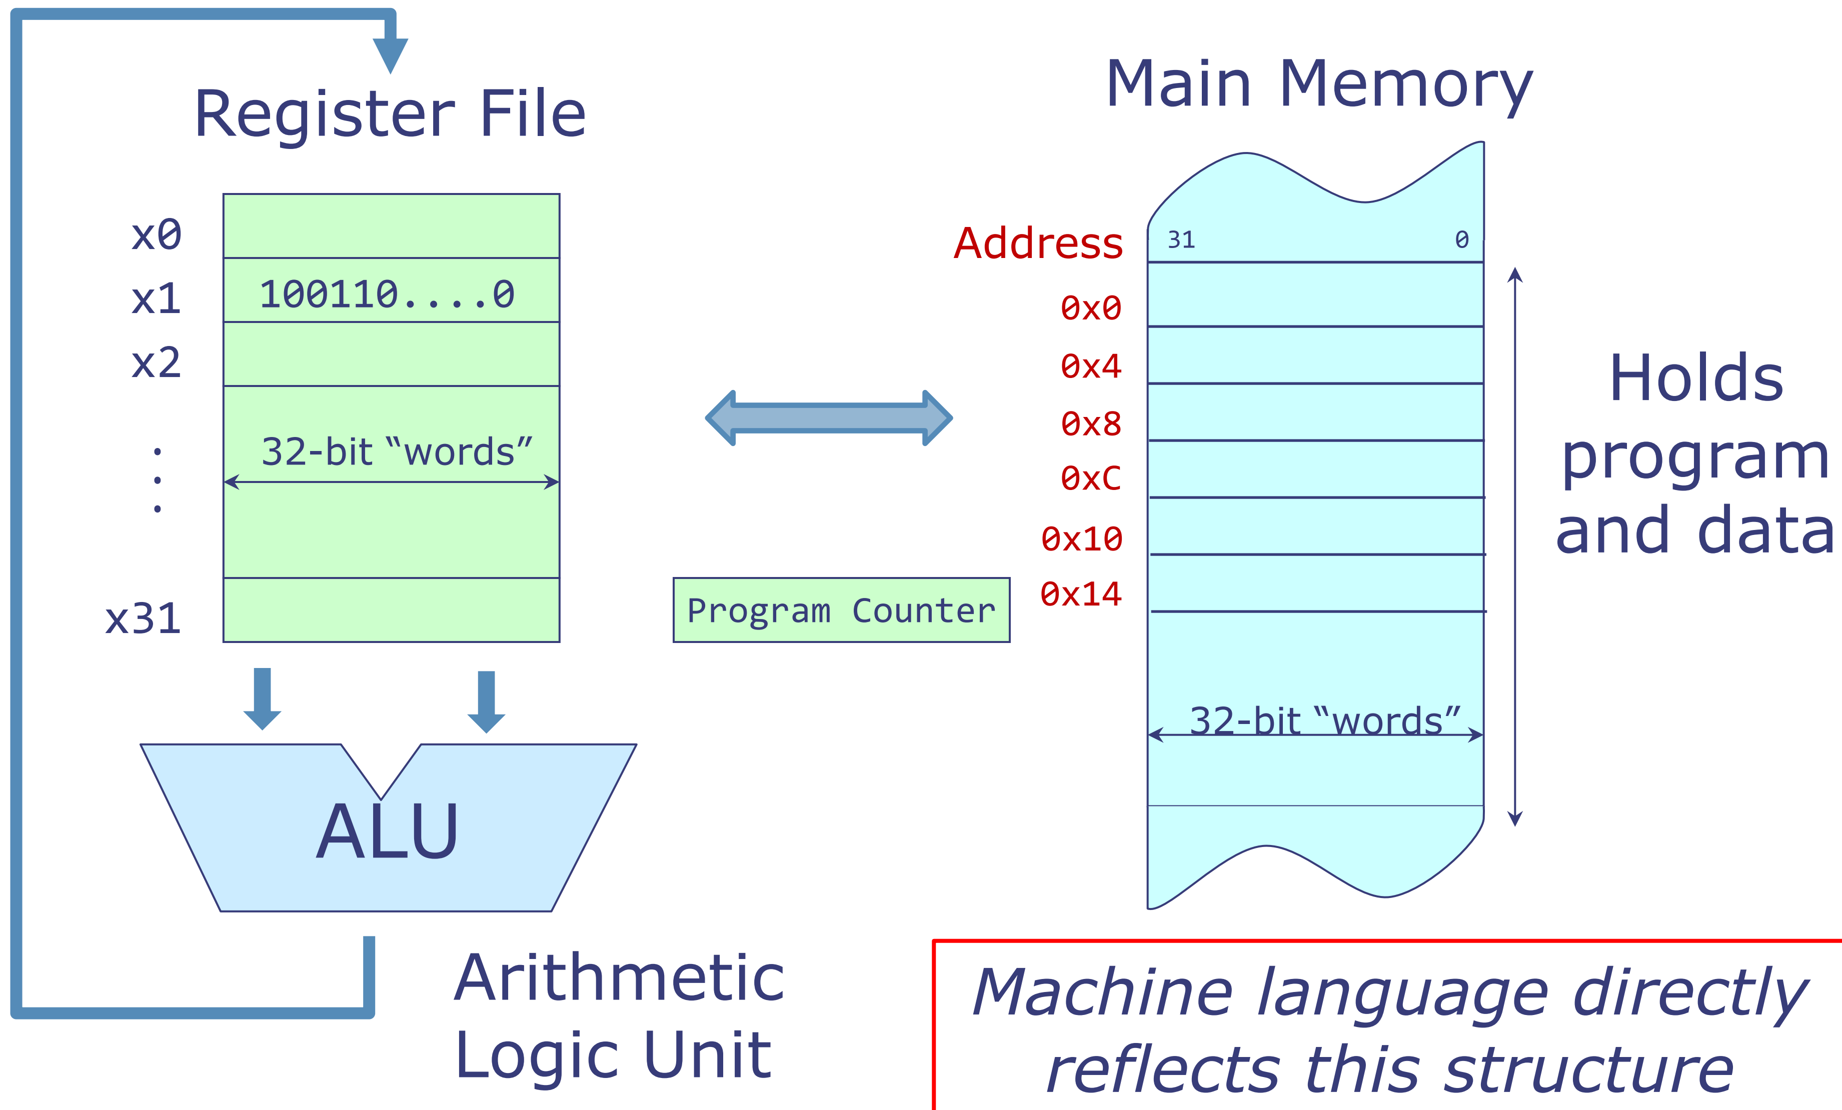
Procedures, Stacks, and MMIO

Reminders:

- Lab 1 due Thursday, 9/17
- Lab 2 will be released today
- Sign up for checkoff for lab 1

Components of a MicroProcessor



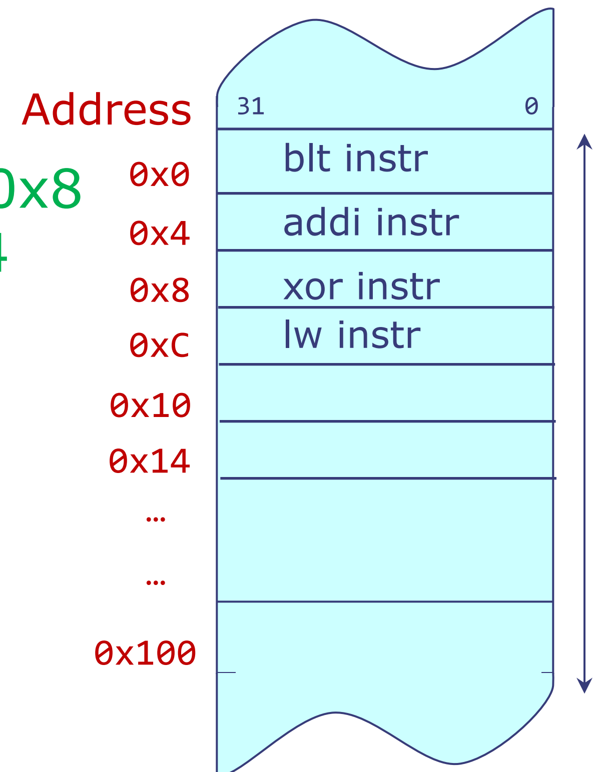
Machine language directly reflects this structure

Program Counter

- The PC register keeps track of the address of your current instruction.
- For non control-flow instructions, PC ← PC + 4
- Instructions and data are stored as 32-bit binary values in memory.

```
        . = 0x0
        blt x1, x2, label        if x1 < x2: PC ← 0x8
                                 else: PC ← PC + 4
        addi x1, x1, 1
label:  xor x2, x1, x1
        lw x3, 0x100(x0)         x3 = 0x12345678

        . = 0x100
        .word 0x12345678
```



Recap: RISC-V Calling Convention

- The calling convention specifies rules for register usage across procedures

Symbolic name	Registers	Description	Saver
a0 to a7	x10 to x17	Function arguments	Caller
a0 and a1	x10 and x11	Function return values	Caller
ra	x1	Return address	Caller
t0 to t6	x5-7, x28-31	Temporaries	Caller
s0 to s11	x8-9, x18-27	Saved registers	Callee
sp	x2	Stack pointer	Callee
gp	x3	Global pointer	---
tp	x4	Thread pointer	---
zero	x0	Hardwired zero	---

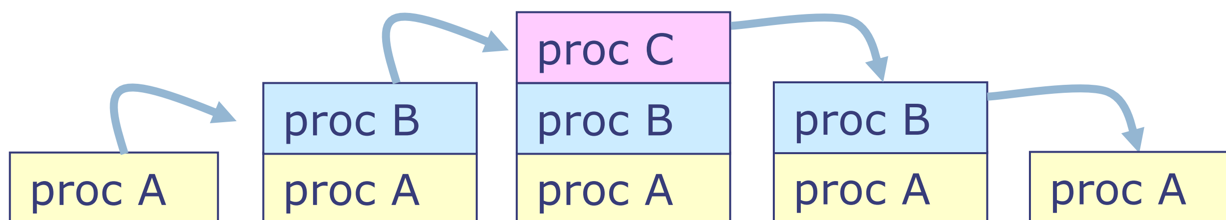
Caller-Saved vs Callee-Saved Registers

- A caller-saved register is not preserved across function calls (callee can overwrite it)
  - If caller wants to preserve its value, it must save it before transferring control to the callee
  - argument registers (aN), return address (ra), and temporary registers (tN)

- A callee-saved register is preserved across function calls
  - If callee wants to use it, it must save its value and restore it before returning control to the caller
  - Saved registers (sN), stack pointer (sp)

Activation record and procedure calls

- An *Activation record* holds all storage needs of procedure that do not fit in registers
  - A new activation record is allocated in memory when a procedure is called
  - An activation record is deallocated at the time of the procedure exit
- Activation records are allocated in a stack manner (Last-In-First-Out)



- The current procedure's activation record (a.k.a. stack frame) is always at the top of the stack

RISC-V Stack

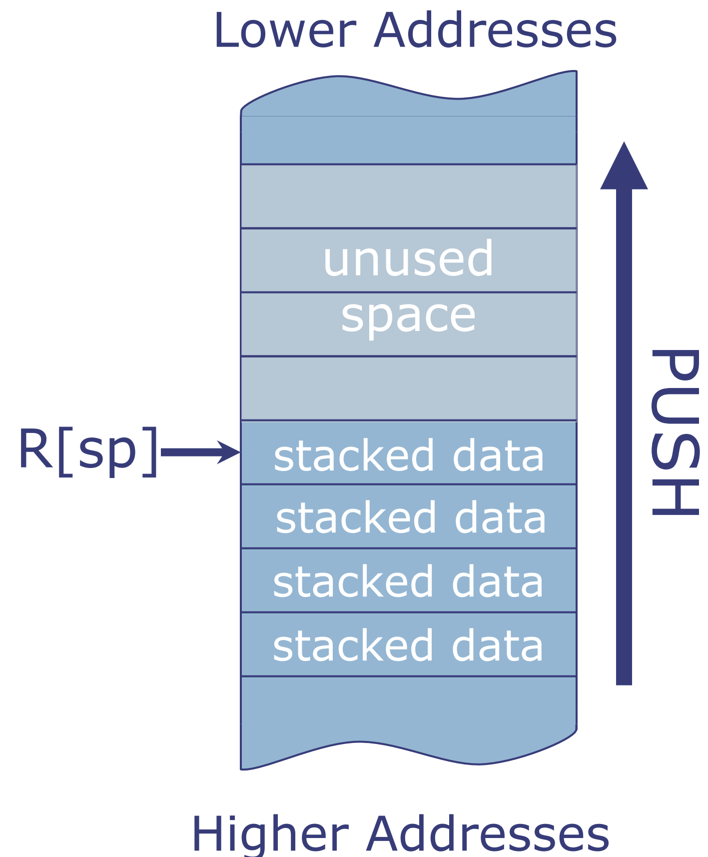
- Stack is in memory
- Stack grows down from higher to lower addresses
- sp points to top of stack (last pushed element)
- Push sequence:

```
addi sp, sp, -4
sw a1, 0(sp)
```

- Pop sequence:

```
lw a1, 0(sp)
addi sp, sp, 4
```

- Discipline: Can use stack *at any time*, but leave it as you found it!



Using the stack for procedures

Sample entry sequence

```
addi sp, sp, -8
sw ra, 0(sp)
sw a1, 4(sp)
```

Corresponding exit sequence

```
lw ra, 0(sp)
lw a1, 4(sp)
addi sp, sp, 8
jr ra
```

Example: Using callee-saved registers

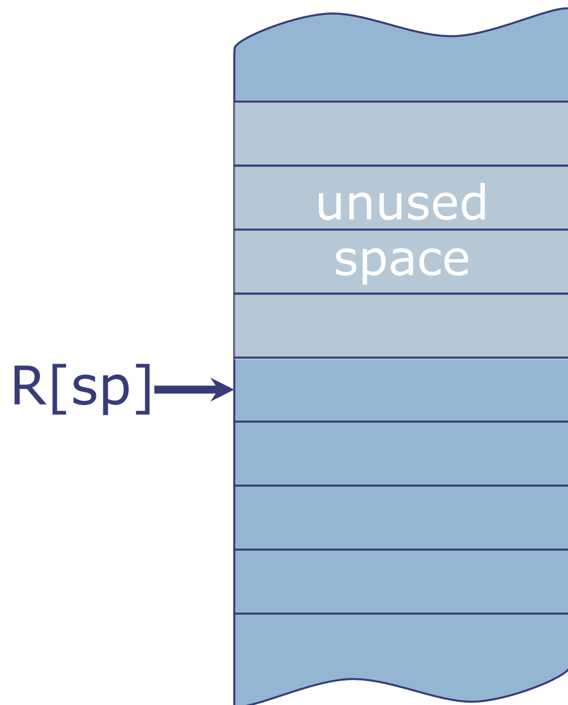
- Implement f using s0 and s1 to store temporary values

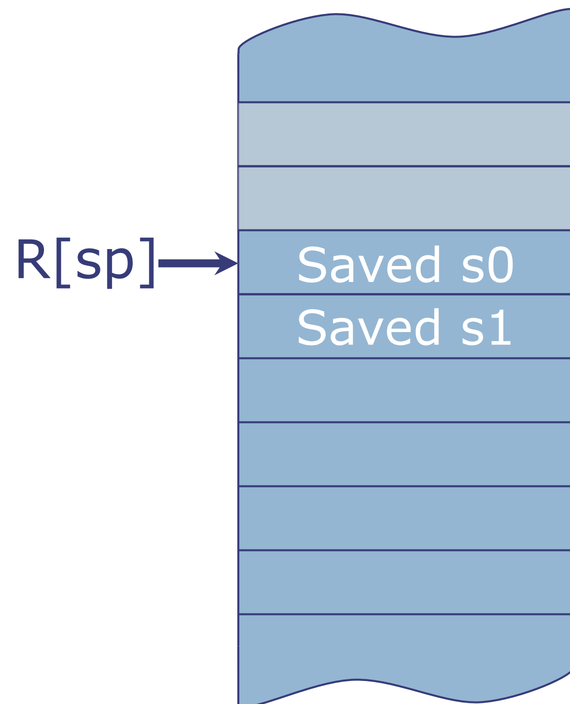
```
int f(int x, int y) {
    return (x + 3) | (y + 123456);
}
```

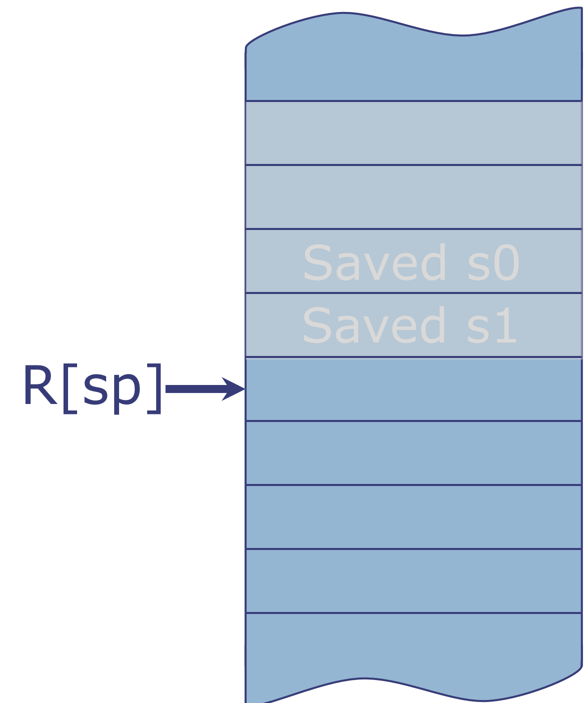
```
f:
  addi sp, sp, -8     // allocate 2 words (8 bytes) on stack
  sw s0, 0(sp)        // save s0
  sw s1, 4(sp)        // save s1
  addi s0, a0, 3
  li s1, 123456
  add s1, a1, s1
  or a0, s0, s1
  lw s0, 0(sp)        // restore s0
  lw s1, 4(sp)        // restore s1
  addi sp, sp, 8      // deallocate 2 words from stack
                      // (restore sp)
  jr ra
```

Example: Using callee-saved registers

- Stack contents:







Example: Using caller-saved registers

Caller

```
int x = 1;
int y = 2;
int z = sum(x, y);
int w = sum(z, y);
```

```
li a0, 1
li a1, 2
addi sp, sp, -8
sw ra, 0(sp)
sw a1, 4(sp) // save y
jal ra, sum
// a0 = sum(x, y) = z
lw a1, 4(sp) // restore y
jal ra, sum
// a0 = sum(z, y) = w
lw ra, 0(sp)
addi sp, sp, 8
```

Callee

```
int sum(int a, int b) {
    return a + b;
}
```

```
sum:
  add a0, a0, a1
  ret
```

Why did we save a1?

Callee may have modified a1 (caller doesn't see implementation of sum!)

Calling Conventions Summary

Caller: Saves any aN, tN, or ra registers, whose values need to be maintained past procedure call, on the stack prior to proc call and restores it upon return.

```
addi sp, sp, -8
sw ra, 0(sp)
sw a1, 4(sp)
call func
lw ra, 0(sp)
lw a1 4(sp)
addi sp, sp, 8
```

```
func:
```

Callee: Saves original value of sN registers before using them in a procedure. Must restore sN registers and stack before exiting procedure.

```
func:
    addi sp, sp, -4
    sw s0, 0(sp)
    …
    lw s0, 0(sp)
    addi sp, sp, 4
    ret
```

Nested Procedures

- If a procedure calls another procedure, it needs to save its own return address
  - Remember that `ra` is caller-saved
- Example:

```
bool coprimes(int a, int b) {
  return gcd(a, b) == 1;
}
```

```
coprimes:
  addi sp, sp, -4
  sw ra, 0(sp)
  call gcd                    // overwrites ra
  addi a0, a0, -1
  sltiu a0, a0, 1
  lw ra, 0(sp)
  addi sp, sp, 4
  ret                         // needs original ra
```

Computing with large data structures

- Suppose we want to write a procedure that finds the maximum value in an array a[].
  - Assume the array is too large to be stored in registers
- We will compare each element of a[] to the max value found so far, and update the max if a[i] is larger than current max.
- How do we pass the array a[] as an argument?
  - Pass the base address and the size of the array as arguments

Passing Complex Data Structures as Arguments

```c
// Finds maximum element in an
// array with size elements
int maximum(int a[], int size)
{
   int max = 0;
   for (int i = 0; i < size;
    i++) {
      if (a[i] > max) {
         max = a[i];
      }
   }
   return max;
}

int main() {
   int ages[5] =
      {23, 4, 6, 81, 16};
   int max = maximum(ages, 5);
}
```

Passing Complex Data Structures as Arguments

```
main:   li a0, ages
        li a1, 5
        call maximum
        // max returned in a0
```

```
ages:   23
        4
        6
        81
        16
```

```c
int main() {
   int ages[5] =
      {23, 4, 6, 81, 16};
   int max = maximum(ages, 5);
}
```

Passing Complex Data Structures as Arguments

```c
// Finds maximum element in an
// array with size elements
int maximum(int a[], int size)
{
    int max = 0;
    for (int i = 0; i < size;
     i++) {
        if (a[i] > max) {
          max = a[i];
        }
    }
    return max;
}

int main() {
    int ages[5] =
        {23, 4, 6, 81, 16};
    int max = maximum(ages, 5);
}
```

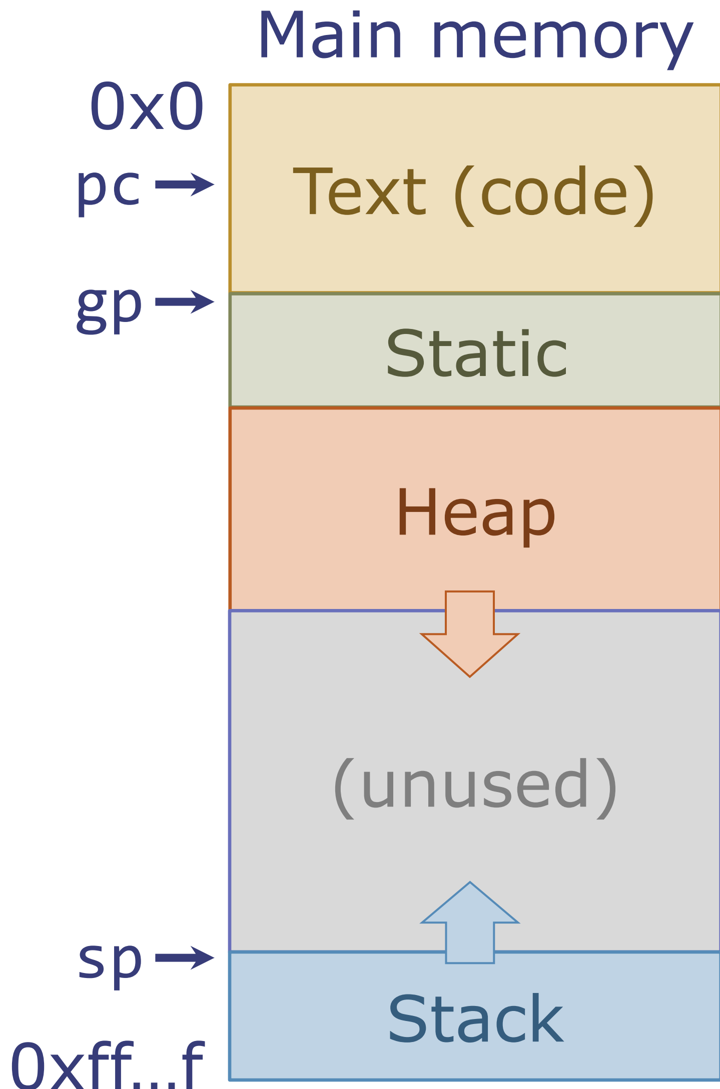
```
maximum:
    mv t0, zero    // t0: i
    mv t1, zero    // t1: max
    j compare
loop:
    slli t2, t0, 2 // t2: i*4
    // t3: addr of a[i]
    add t3, a0, t2
    lw t4, 0(t3)   // t4: a[i]
    ble t4, t1, endif
    mv t1, t4      // max = a[i]
endif:
    addi t0, t0, 1 // i++
compare:
    blt t0, a1, loop

    mv a0, t1  // a0 = max
    ret
```

Memory Layout

- Most programming languages (including C) have three distinct memory regions for data:
  - Stack: Holds data used by procedure calls
  - Static: Holds global variables that exist for the entire lifetime of the program
  - Heap: Holds dynamically-allocated data
    - In C, programmers manage the heap manually, allocating new data using `malloc()` and releasing it with `free()`
    - In Python, Java, and most modern languages, the heap is managed automatically: programmers create new objects (e.g., `d = dict()` in Python), but the system frees them only when it is safe (no pointers in the program point to them)
- In addition, the text region holds program code

RISC-V Memory Layout



- Text, static, and heap regions are placed consecutively, starting from low addresses
- Heap grows towards higher addresses
- Stack starts on highest address, grows towards lower addresses

- sp (stack pointer) points to top of stack
- gp (global pointer) points to start of static region
- pc (program counter) points to the current instruction

Handling Inputs and Outputs

Used in Lab 2

Accessing Inputs and Outputs

- Programs may want to print output to a display
- Programs may want to receive input from a keyboard
- Assign special addresses to represent I/O devices
  - Can execute **lw** or **sw** instructions to these addresses to access the devices.

Memory Mapped I/O (MMIO)

- Assign dedicated addresses to I/O devices
- MMIO addresses can only be used for I/O and not for regular storage.
- I/O Devices monitor the processor memory requests and respond to memory requests that use the address associated with the I/O device.

MMIO Addresses

- Inputs
  - 0x 4000 4000 - performing a **lw** from this address will read one signed word from the keyboard.
  - Repeating a **lw** to this address will read the next input word and so on.

- Outputs:
  - 0x 4000 0000 - performing a **sw** to this address prints an ASCII character to the console corresponding to the **ASCII** equivalent of the value stored at this address
  - 0x 4000 0004 - a **sw** to this address prints a **decimal** number
  - 0x 4000 0008 - a **sw** to this address prints a **hexadecimal** number

Memory Mapped IO Example 1

Program that reads two inputs from keyboard, adds them, and displays result on monitor.

```
// load the read port into t0
li t0, 0x40004000

// read the first input
lw a0, 0(t0)
// read the second input
lw a1, 0(t0)

// add them together
add a0, a0, a1

// load the write port into t0
li t0, 0x40000004
// write the output in decimal
sw a0, 0(t0)
```

MMIO for Performance Measures

- Performance Measures
  - 0x 4000 5000 – **lw** to get **instruction count** from start of program execution
  - 0x 4000 6000 – **lw** get **performance counter** – number of instructions between turning the performance counter on and then off.
  - 0x 4000 6004
    - **sw 0** to turn **performance counting off**
    - **sw 1** to turn it **on**

Memory Mapped IO Example 2

```
// prepare to read input from console
li t0, 0x40004000
// get user input
lw a0, 0(t0)
lw a1, 0(t0)
// load the performance counter address into t1
li t1, 0x40006000
li t2, 1
// start the performance counter by storing 1 to the magic address
sw t2, 4(t1)
add a0, a0, a1
// stop the performance counter by storing 0 the the address
sw zero, 4(t1)
// prepare to print decimal to console
li t0, 0x40000004
// first print sum
sw a0, 0(t0)
// get the count from the performance counter
lw t2, 0(t1)
// print the count
sw t2, 0(t0)
```

Thank you!
